> lust night enabling technologies have made it possible for the aircraft to fly exacting missions during 1th But, the human being is faced with a variety of problems due to changes in bio-rhythms. This nor discusses some problem areas related to extended night flying and highlights the importance disc co-operation between flying unit personnel and the aero medical community. The paper also nommends measures to enhance night capability along with improved flight safety.

UASM 2000; 44(2): 45-50

III WORDS: Aircrew fatigue, Night flying, Extended night flying

In the past, night missions have been flown I only during contingency situations.

Today, battle space is considered four measional. Along with night, depth and breadth of battle field; time has become an important omponent of warfare and it continues to change reimportance of Center's of Gravity (COG). A key aget of the moment could soon become unassailthe if not attacked in time.

In our subcontinent key movement of unface forces take place at night. Furthermore, and attacks keep a continual pressure on the tumy's AD capability and deny him vital time for ma cooling, servicing and repairs. Thereby lemding his offensive potential, interfering with mus of his airfields, imposing psychological passure and creating confusion and harassment. Therefore the side, which is able to carry out night

strikes, is likely to have a decisive edge in future operations. Hence, it is imperative that IAF should have a 24 hour and dedicated night capability which integrates technology, doctrine and force structure. This paper highlights the problem areas during extended night operations and suggests remedial measures [2].

Dedicated Night Strike Capability

Few squadrons of IAF have been assigned with the task of performing dedicated night strikes. These squadrons are engaged in carrying out extended night operations on regular basis.

Key Issues

- Classified Specialist Aerospace Medicine,
- Commanding Officer, 18 Squadron AF

Extended night operations: Modak

Key Issues

Circadian Rhythm

Human being experience a regular cycle of sleep and wakefulness, which has a constant relationship with the day-night cycle. Day-light and darkness are the most important environmental influence on this circudian rhythm. Disturbance in the environment and unusual patterns of work are likely to change the sleep-activity cycle of circadian rhythm. Figure 1 shows the average range for human core body temperature. Sleep normally corresponds with the section of the curve where core body temperature and alertness level is low. A schedule that routinely conflicts this cycle can be expected to predictable difficulties in obtaining adequate sleep and lead to associated decrements in performance both short term and cumulative [1].

Sleep physiology

The sleep physiology of human beings could best be understood with the help of a graph Figure-2. The X axis displays the time of the day and latency to drowsy sleep is reflected in the Y axis (time in minutes). The graph could similarly be plotted for night also [1].

An analysis of the sleep latency test clearly indicates that a person feels drowsy between 1400-1600h and again after 2200h. During this time period, the alertness level of most individuals is lower and his ability to concentrate lesser. Hence, chances of committing a mistake in a skilled task would be higher.

Night operations

The night operations have inherent

differences with day flying. These includes external visual references, loss of day perception, chances of disorientation and in to fly at extreme low altitudes. Hence, niftly is inherently more stressful and demanding routine flying activities need more concern at night than that required during day time

Technology Limitations

The fighter ac available with IAFvo assigned for extended night roles has tem limitations. There are no night vision deve spirit. there is a lack of accurate night navigationa as well as precise targeting equipment. He increased performance is required from in even to carry out routine flying activities increased performance requirement puts by under additional stress and adds to the curre stress burden at night especially during our night operations.

WORKING HOURS OF A SQUADRON

It is well known that the working he unrealist an Sqn is longer than any base working to sleep, m These working hours, without adequaterests and dem in between, is liable to cause cumulatives beneficia over a period of time.

CASO Restrictions : Aircrew Fatigue

Considering the stress involved with flying, the CASO'S stipulate a few restriction

- (a) Night flying beyond 2400h for no than three consecutive nights.
- (a) (b) Minimum ten hours gap between con cold, noi of night flying to commencement di relates to flying.

een cessation

- (c) Nonnal duty period should be eight hours and maximum should not exceed ten hours. The station working hours should not govern the working hours of a unit.
- id if aircrew is required to be on duty for periods in excess of ten hours on three consecutive occasions, a 24-hour period should clapse before resuming flying

his difficult to follow the CASO in letter and the primary reason is that the station wing hours commence from 0700h. Therefore as briefings; parades, Boards of Officers, Duty offer and other station duties need to be anded to during thise time period.

WERENT TYPES OF STRESS

Stress should be as defined as physiological some to the pressures of daily routine and is ad for affective living [2]. Stress could be due I conflict with co-workers/family members. stalistic expectations, work pressure, lack of en money worries, inadequate self confidence addemand of quality. Some amount of stress is reficial as it raises the alertness level and makes human being perform better. Also stress is mustry for achievement of goals. However, amilative stress beyond a threshold level (which we from individual to individual) is harmful and to performance graph of the individual drops omiderably thereon.

knwcould be classified as follows: -

(a) Environmental (physical). This is due to and noise and vibrations. Also in aviation, it tals to higher stress level during night flying.

(b)Environmental (working environment/

Human relationships). Martial problems or problems with children put additional burden on the aviator. Also, the entire environment surrounding the aircrew is geared to work during day and sleep by night. The aviator involved in dedicated night strike squadrons is unable to devote adequate prime time towards children's education, social engagements and wife. This results in fraction and demand on the aviator to devote time from his rest time towards family/social activities. This type of stress is equally important to all personnel on ground including technical, ATC, Met and flight safety who are actively involved in flying operations.

- (c) Psychological the psychological stress relates to G effect, disorientation and health problems. This stress considerably reduces the pilot's situational awareness and his ability to react correctly to changed circumstances.
- (d) Reactive this stress essentially relates to response towards emergent and unforeseen or unfamiliar situations.

EFFECTS OF EXTENDED NIGHT FLLYING AND EXTENDED WORKING HOURS

Extended night flying implies flying at extended durations in a 24/48-hour period. With less number of qualified pilots for extentended night operation in a squadron, some aircrew needed to fly even 05 hours per day. In some aircraft without autopilot, night operations did add additional stress to the pilot. Some of the experiences of extended night flying are highlighted in the succeeding paragraphs.

Sleep loss. Though sleep requirements vary considerably, it is generally perceived that six to eight hours of sound sleep per day is a requirement. Sleep loss affects the quality of thinking, concentration ability and decision making capability. Sleep loss also results in fatigue and increased stress level. As this is cumulative, there is a deterioration in the performance of the aircrew, technical personnel and traffic controllers. Thereby making them liable to commit mistakes during stressful situations.

Sleep loss and fatigue could lead to the following: -

- Complacency. Easier acceptance of substandard performance.
- Computational and Navigational errors. Mathematical and abstractional abilities are reduced.
- (c) Degradation in Human performance. There is a marked reduction in human performance to carry out routine tasks.
- (d) Communication Errors. Ability to communicate effectively gets degraded.
- Sense of Disjointment. Feeling of being alone especially while flying during late night hours with limited external lights and less number of ac flying.
- Reduced situational Awareness, Ability to respond to changed circumstances or stressful situations reduces.
- Disorientation. Fatigue increases chances of disorientation (especially at night). It is possible that the accidents at night due to disorientation could be resulting from cumulative fatigue as one probable cause. Disorientation could be of the following types.
 - (i) Empty Field myopia Relative short sightedness in flight.
 - (ii) False Reference. Stars near the horizon are mistaken for lights on ground. Also, whilst engaging clouds at night, changes of false reference is very high.

- (iii) Autokinetic illusion. Staring at allo lights leads to movement of the light areas.
- (iv) Occulogravic illusion. Gives a less nose up attitude of ac while the sin accelerating on ground.
- Psychological Effects, Sleep loss and slowly result in psychological irritation and quarrelsome nature. There ing to demoralization over a penotor
- Reduced Ability to combat stress. See should be (i) and fatigue reduces the ability of the and personnel to combat stress and fire tendency to give up in stressful saufi

REMEDIAL MEASURES.

There is no doubt regarding here 24 hrs operations. At the same time, in potential problems related to extended night open with mo Both these needs could be meshed a should a provided certain issues are tackled in the capability spirit and there-by meeting both our acquisition requirements and flight safety consider squadron Some of the measures required are combelow.

Co-Location of Night strikes squa with enh Though op location could be differ work on peacetime location of both dedicated night might we squadrons should be at one base. This capability optimize the working hours of all the a flight sa involved with night operations. Besides a chosen in better and efficient maintenance of nightme displayed (as and when the Mig-27 ac are fin squadror improved avionics and night vision device to the N squadron's incumbent responsibility a could tal station duties would also get optimize day task station working hours could start in the after training and end at night. This would ensure frother air squadron need not work from 0700 has should morning till 2400 hrs at nigh, thereby a squadron

making fatigue and excess working hours making reduced output. Additionally, the miniment around the night squadron itself sudnow be in consonance with night operations, amby reducing overloaded on all agencies moved in flying operations. In case jaguar qualress are given dedicated night capability, attin placement of two jaguar (night) squadrons are base could be considered an option.

Continuity of Night operations: Night flying took be planned on consecutive days; not more to five days and not more than two weaks in much (preferably alternate weeks). This block who of training would ensure that biorhythins if the personnel adjust to night operations moliculty.

Mig-27 ac up gradation: To enhance combat similal and reduce pilot stress, equipping them at modern avionies and night vision devices tail enhance the Mig-27 ac's performance publicy and reliability. In the night equipment quition process, the dedicated night strike gaton personnel should also be integrated.

Changes in force structure: The night strike andron could be split into two-flight structure thenhanced manpower. The two flights should arkon day/night shifts for that week on alternate pt week basis. This would ensure that 24 h ability is retained within the squadron and yet let safety is not compromised. The personnel from for the dedicated squadron should have inhyed better night performance in their previous andons. No ops U/T aircrew should be posted ade Night strike squadron (One single aircrew mil take away as much as 25-30% of available by task). This would reduce operational day ming hours available with the squadron for the aircrew. Only ops day/Fully ops on type wild be posted to dedicated night strike studion.

Physical litness: It is a known fact that physically fit individuals are less prone to disorientation and are more capable of handling combat stress as well as cumulative fatigue. Fully equipped gyms should be provided at squadrons and time should be made available to utilize these facilities. Even Gym utilization (three days a week) in morning/evening could be made compulsory depending on the officers work shift.

Role of Aeromedical officer: An Aeromedical officer would need to be a part and parcel of the dedicated night strike Squadron. He/She would have to closely integrate with the squadron personnel (officers and airmen) including their families. Also, he/she would have to play the role of a psychotherapist. The need would be to assess individual stress levels and to identify cumulative fatigue signals. Thereafter advice the commanding officer on corrective measures. Also, the medical officer would need to regularly counsel the squadron personnel as a whole.

Education of families: Education of families in recruiting their understanding and support will play vital role in conserving flight safety. It is here that AOC/Sin Cdr and doctors have a major role to play.

Leave periods and exercise durations: The best method to counter cumulative fatigue is regular and periodical leave. It should be ensured that in every six months all personnel of the squadron take at least two weeks of continuous leave. Squadron detachments and courses should be streamlined at the Air HQ level in a focused manner so that an aircrew is not out of his peacetime location for more than eight to ten weeks at a time (except lone term professional courses)
